map

A US-states or world-countries basemap that fills regions by value (choropleth) or category (highlight) so the audience leaves knowing where.

Grant dollars reached every region — unevenly.

The four regions we serve.

Where our field offices operate.

Coverage by economic bloc.

Where our field offices operate.

A wide spread across fifteen states.

Grant dollars reached every region — unevenly.

Grant dollars reached every region — unevenly.

Grant dollars reached every region — unevenly.

When NOT to reach for map.

A map as decoration.

If the regions aren't the comparison — you just want a US-shaped graphic behind some numbers — drop the basemap. An

image

scrim
or a

stats

row carries headline figures without implying the geography is the message.

Too many shades to read Sub-region

A choropleth past a dozen distinct values asks the eye to rank colours it can't separate. Bucket the values, switch to

highlight

for a categorical read, or lead with a

progress

ranking and keep the map as support.

precision the basemap doesn't have.

The basemaps draw US states and world countries — not counties, districts, sub-national regions, or city pins, and the world cut (110m) omits the smallest city-states. If the story lives below that line, a labelled

image

of the real map serves better than forcing it onto the basemap.

RELATED COMPONENTS

See also.

- `progress` — the regions are really a ranking — labelled bars compare magnitudes faster than shades
- `stats` — a few headline figures with no geography to place them on
- `piechart` — regional shares of a single whole rather than a value per place
- `image` — the geography needs detail (counties, cities, routes) the states basemap can't draw
