

COMPARISON · SPLIT · STRUCTURE

before-after

Explicit state-change comparison — what was, what is.

What the manifest refactor produced.

BEFORE.

35 layouts scattered across one 10,382-line lattice.css monolith. Per-layout rules grepped, not folder-located. No central metadata.

AFTER.

45 components self-contained at lib/components, one folder each with manifest plus styles plus example plus README. Bundler concatenates per-component CSS; loader exposes the catalog via JSON.

When NOT to reach for before-after.

Two competing options. Use `compare-prose` or `split-compare` when both sides are alternatives under consideration. before-after is for a change that already happened.

More than two states. If there is a middle state or a sequence of changes, use `list-steps` to show the progression. before-after is binary by construction.

Editorial labels on the cards. The card label is always Before or After. Renaming them to Old way / New way defeats the universal grammar and breaks reader expectations.
